Accepted for publication 26 June 1989

Summary Six leprosy patients in the Ridley–Jopling spectrum of BT–BL showing lesions on penis and scrotum are presented, as we believe that this common enough clinical feature is not well documented in the literature.

Introduction
Groin, perineum along with scalp, axilla and the narrow band of lumbosacral area are considered to be ‘immune zones’ in leprosy. To the best of our knowledge, clinical involvement of genitals in leprosy has not been well documented in the literature. We report six cases of leprosy, showing involvement of male external genitalia. Lesions on the external genitalia may be encountered in leprosy of all types in the entire Ridley–Jopling spectrum. It is however not known whether lesions due to indeterminate leprosy, representing the earliest clinical manifestation of the disease, can occur in these organs.

Case reports
We report six cases with leprosy lesions ranging from BT to BL types with clinical photographs (Figures 1 and 2) showing involvement of the penis and the scrotum.

All six patients had borderline leprosy of more than 6 months duration. Three patients had lesions on glans penis. Two cases were in Type I lepra reaction. The slit-smear examination was positive in four cases.

Observations and conclusions
It is known that Mycobacterium leprae has a distinct predilection for the cooler areas of the body. Anish1 demonstrated higher temperature of the axilla and scalp as compared to that of the forearm.

Sahni et al.2 studied 20 untreated BL and LL cases. They observed groin involvement clinically in five cases, skin-smear positivity in three, while all showed histological changes. Bedi et al.3 observed histological involvement of groin in 10 out of 20 LL patients under monotherapy. Pandya
Figure 1. Case No. 2. Erythematous annular lesion on the scrotum.

Figure 2. Case No. 6. Hypopigmented dry scaly patch on the scrotum with partial loss of sensation.

& Antia studied scrotal skin and underlying dartos biopsies from 45 patients suffering from various types of leprosy (12 TT, 22 borderline & 11 LL) most of them treated. In almost all the cases histology showed involvement of the neurovascular bundles. According to them, scrotal skin involvement is due to a liberal supply of larger nerves as compared to cutaneous nerves elsewhere.

If the clinical examination of any male leprosy patient is to be considered exhaustive, it must include examination of external genitalia.
